Lab 7

Optimizing GPT-2 with KL Regularization + DPO

Today you will:

1. Do a warm-up update that penalizes drift from a reference model via KL
2. Train with Direct Preference Optimization (DPO) using your Lab 6 preference pairs
3. Evaluate base vs KL-only vs DPO models on held-out prompts
4. Reflect on how human feedback can fail (shortcut learning, ambiguity, drift)

Note: We are not trying to "fully align" GPT-2. We're trying to see how optimization amplifies your feedback signal.

Run on Google Colab:

Open in Colab

```
!nvidia-smi -L
```

```
GPU 0: Tesla T4 (UUID: GPU-4f3a815f-1fb7-d21e-0925-a9a78d5d6383)

(1, 1)
```

“KL to a reference” (no preferences yet)

We’ll do a tiny “behavior cloning on chosen responses” update with an explicit KL penalty to a frozen reference model

We do a small supervised update on the **chosen** responses, but we add a KL penalty so the updated policy stays close to the base model.

Conceptual objective:

$L = -E[\log \pi\theta(y|x)] + \beta\, KL(\pi\theta \,||\, \pi_ref)$

Interpretation:

- First term: "imitate chosen text"
- KL term: "don't drift too far from reference"

```
MODEL_NAME = "gpt2"

tokenizer = AutoTokenizer.from_pretrained(MODEL_NAME)
if tokenizer.pad_token is None:
    tokenizer.pad_token = tokenizer.eos_token

policy = AutoModelForCausalLM.from_pretrained(MODEL_NAME).to(device)
ref    = AutoModelForCausalLM.from_pretrained(MODEL_NAME).to(device)

ref.eval()
for p in ref.parameters():
```

```
    p.requires_grad_(False)

print("Loaded.")
```

```

Once the model already separates them well, σ saturates near
so updates stop, it naturally ignores already-learned pairs.
```

Checkpoint

Explore different values for β. Were you correct in your prediction in the previous checkpoint?

> **It pushes the model to favor the chosen response over the rejected one. Once the model already separates them well, σ saturates near 1 and log σ → 0, so updates stop, it naturally ignores already-learned pairs.**

Direct Preference Optimization (DPO)

We directly optimize the policy so that, for each prompt x:

- y^+ (chosen) becomes more likely than y^- (rejected),
- while staying close to a reference model.

Core DPO form (conceptual):

$\log \sigma(\beta (\log \pi\theta(y^+|x) - \log \pi\theta(y^-|x)))$

Key contrasts vs RLHF:

- No explicit reward model
- No sampling loop (no PPO rollout step)
- Just preference pairs + likelihood ratio

```
# We'll train a separate DPO model from scratch starting at base gpt2
dpo_model = AutoModelForCausalLM.from_pretrained(MODEL_NAME).to(device)
dpo_ref   = AutoModelForCausalLM.from_pretrained(MODEL_NAME).to(device)
dpo_ref.eval()
for p in dpo_ref.parameters():
    p.requires_grad_(False)

print("DPO models ready.")
```

Checkpoint

Propose one additional automatic signal you wish you could measure here. Why would it be helpful, and why is it hard?

Semantic similarity to the chosen response. This would tell us whether the model's output is meaningfully closer in content to the preferred response rather than just matching length or refusal words. It's hard becasue embedding similarity doesn't perfectly capture factual correctness or safety.
